

# 1 Example Technology: Macromedia Flash & ActionScript

- 1.1 Multimedia authoring tools - Example Macromedia Flash
- 1.2 Elementary concepts of ActionScript
  - Scripting in General + „History“ of ActionScript
  - Objects and Types in ActionScript
  - Animation with ActionScript
- 1.3 Interaction in ActionScript
  - Handling of Mouse Events
  - Classical Model-View-Controller Programming
- 1.4 Media classes in ActionScript

Literature:

Colin Moock: Essential ActionScript 2.0, O'Reilly 2004

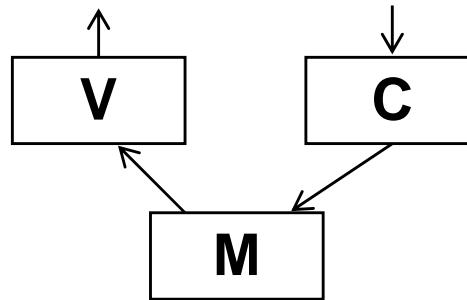

# Creating a “Graphically Enhanced” User Interface

- Traditional programming
  - Example: Account with credit and debit function
- Additional “multimedia” features:
  - Auto-highlighting buttons
  - Visualization of money transfer direction
  - Visualization of “low” warning

# The Account Class

```
class Account {  
  
    var saldo:Number = 0;  
    var num:Number;  
  
    function Account(accnum:Number) {  
        num = accnum;  
    }  
  
    function debit(n:Number) {  
        saldo -=n;  
    }  
  
    function credit(n:Number) {  
        saldo +=n;  
    }  
  
    function getNumber():Number {  
        return (num);  
    }  
  
    function getSaldo():Number {  
        return (saldo);  
    }  
}
```

# Model-View-Controller (MVC) Paradigm

- Model:
  - Business model, mostly independent of user interface
  - Observable by arbitrary objects (application of *Observer* pattern)
- View:
  - Representation on user interface
  - Observes the model
  - Asks required data from the model
- Controller:
  - Modifies values in the model
  - Is driven by user interactions, therefore bound to elements of interface
  - Handles events mainly by calling methods of the model

# Observer Design Pattern

- Classical design pattern, made publicly conscious by Gamma/Helm/Johnson/Vlissides
- Integrated into many frameworks, e.g. Java standard library (SDK)
- Idea:
  - *Observable* is a class from which any class is derived which shall notify other objects of changes
  - *Observer* is an interface through which objects can be notified of changes
    - » Providing a callback method *update*
  - Observable provides a method *notifyObservers* to actually inform observing objects
  - Observers have to register (*addObserver*)

# How to Realize an Observer Mechanism?

- Approach 1: Look for an existing standard mechanism
  - ActionScript: Contains standard class library
  - Possible solution: Use `mx.events.EventDispatcher`
  - However: Not officially documented, not fully identical
- Approach 2: Re-implement the pattern
  - Not difficult for ActionScript, just port the Java library source code
  - Own class library can be defined as a local package or at a central location
- Approach 3: Look for somebody who has already re-implemented the pattern
  - For ActionScript 2 e.g. Colin Moock, author of "Essential ActionScript 2.0"

# Excerpt from util.Observable

```
import util.*;  
  
/**  
 * A Java-style Observable class used to represent the "subject"  
 * of the Observer design pattern. Observers must implement the Observer  
 * interface, and register to observe the subject via addObserver().  
 */  
class util.Observable {  
    // A flag indicating whether this object has changed.  
    private var changed:Boolean = false;  
    // A list of observers.  
    private var observers:Array;  
  
    /**  
     * Constructor function.  
     */  
    public function Observable () {  
        observers = new Array();  
    }  
  
    /**  
     * Adds an observer to the list of observers.  
     * @param o The observer to be added.  
     */  
    public function addObserver(o:Observer):Boolean {  
...  
}
```

# Source Code for util.Observer

```
import util.*;  
  
/**  
 * The interface that must be implemented by all observers of an  
 * Observable object.  
 */  
  
interface util.Observer {  
    /**  
     * Invoked automatically by an observed object when it changes.  
     *  
     * @param o The observed object (an instance of Observable).  
     * @param infoObj An arbitrary data object sent by  
     *                the observed object.  
     */  
    public function update(o:Observable, infoObj:Object):Void;  
}
```

# Model: Observable Account Class

```
import util.*;  
  
class Account extends Observable {  
  
    var saldo:Number = 0;  
    var accNum:Number;  
  
    function Account(an:Number) {  
        accNum = an;  
    }  
  
    function debit(n:Number) {  
        if (n < 0) return;  
        saldo -=n;  
        if (n <> 0){  
            setChanged();  
            notifyObservers(false);  
        }  
    }  
  
    function credit(n:Number) {  
        if (n < 0) return;  
        saldo +=n;  
        if (n <> 0){  
            setChanged();  
            notifyObservers(true);  
        }  
    } ...  
}
```

# View: User Interface Design

- Main output form is a (dynamic) text field
- However:
  - Text fields cannot carry ActionScript code
  - Text field cannot be easily associated with AS class
- How can we stay object-oriented?
- Idea: Add a specific view object which just refers to the visible text field object

The screenshot shows a user interface for a bank application named "SuperBank". At the top, the title "SuperBank" is displayed in a large blue font. Below it, a message reads "Your current account balance is:". To the right of this message is a text input field containing the euro symbol "€" followed by a blank input field. Below this section, there is a label "Amount:" followed by another text input field containing the euro symbol "€". To the right of the amount input field are two blue rectangular buttons labeled "credit" and "debit", each with a small white circle icon above it. The overall design uses a clean, modern aesthetic with blue and white colors.

# Class AccountView

```
import util.*;  
  
class AccountView implements Observer {  
  
    private var saldo_txt:TextField;  
    private var lowWarning_mc:MovieClip;  
    private var myAccount:Account;  
    private var saldo:Number;  
  
    private function animSaldo() {  
        saldo = myAccount.getSaldo();  
        saldo_txt.text = String(saldo);  
        if (saldo < 0)  
            lowWarning_mc.gotoAndPlay("startAnim");  
        else  
            lowWarning_mc.gotoAndStop("stopAnim");  
    }  
  
    public function AccountView(t:TextField, l: MovieClip, a: Account) {  
        saldo_txt = t;  
        lowWarning_mc = l;  
        myAccount = a;  
        myAccount.addObserver(this);  
        animSaldo();  
    } ...
```

# More Animation...

- Extending AccountView to cover an animation for money transfers:
  - Add `credit_mc`, `debit_mc` as constructor parameters and local variables
- Call animation when update is issued by model
  - Depending on direction of money flow as given by info object

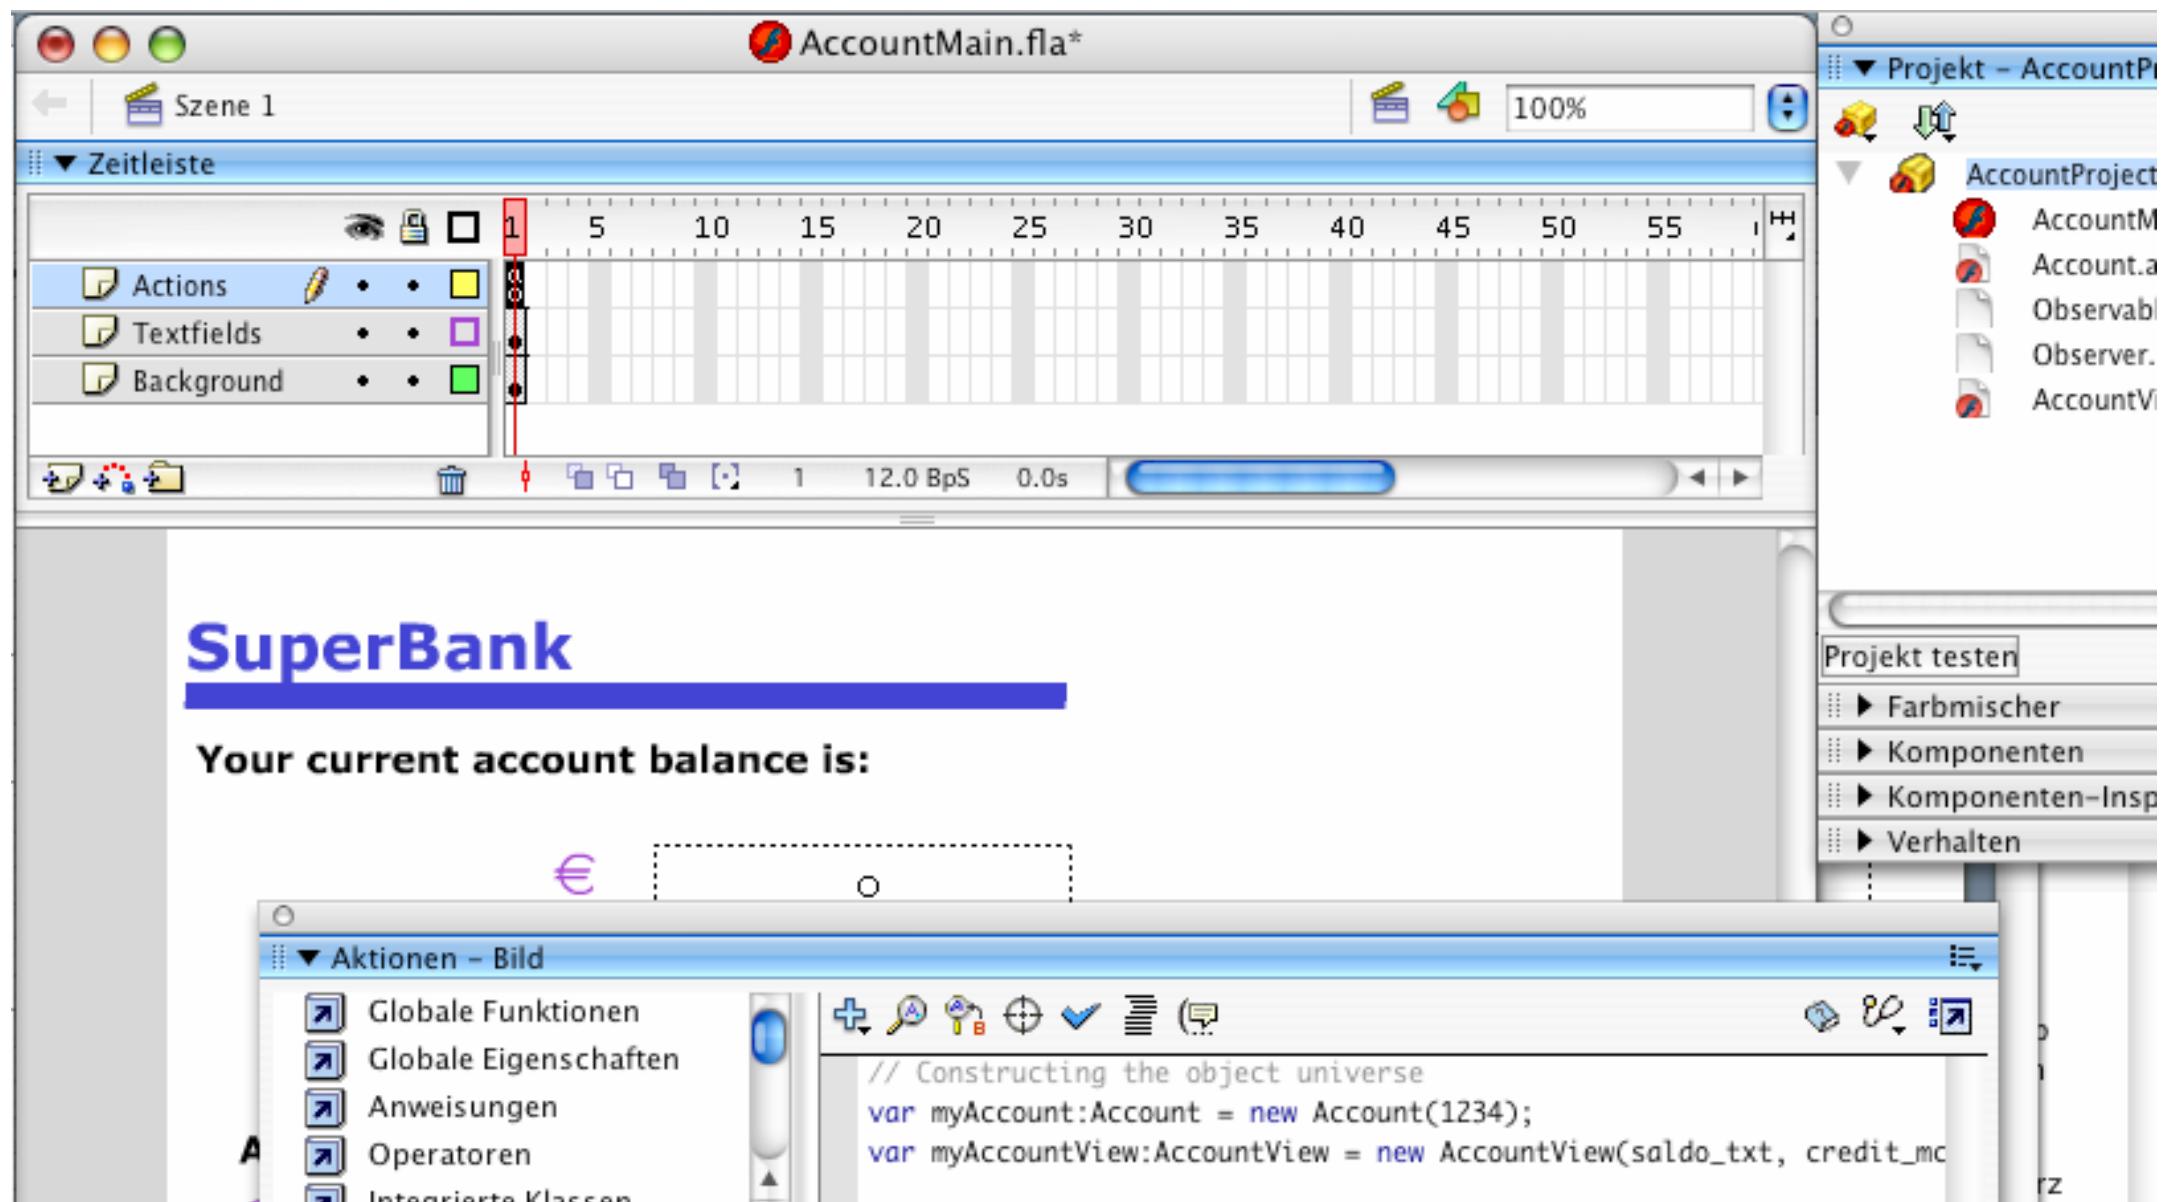

```
public function update
    (o:Observable, infoObj:Object):Void {
    var credit:Boolean = Boolean(infoObj);
    if (credit)
        credit_mc.gotoAndPlay("startAnim");
    else
        debit_mc.gotoAndPlay("startAnim");
    animSaldo();
}
```

# Controller: User Event Handling

- Using Flash's built-in **Button** class makes highlighting easy.
- Event handling code (example “credit”, “debit” is similar):

```
on (release) {  
    var amount:Number = Number(amount_txt.text);  
    if (isNaN(amount) or (amount < 0)) {  
        amount_txt.text += "?";  
    }  
    else {  
        myAccount.credit(amount);  
    }  
}
```

# Constructing the Objects in Main Timeline

# Alternative: Extending a TextField Object

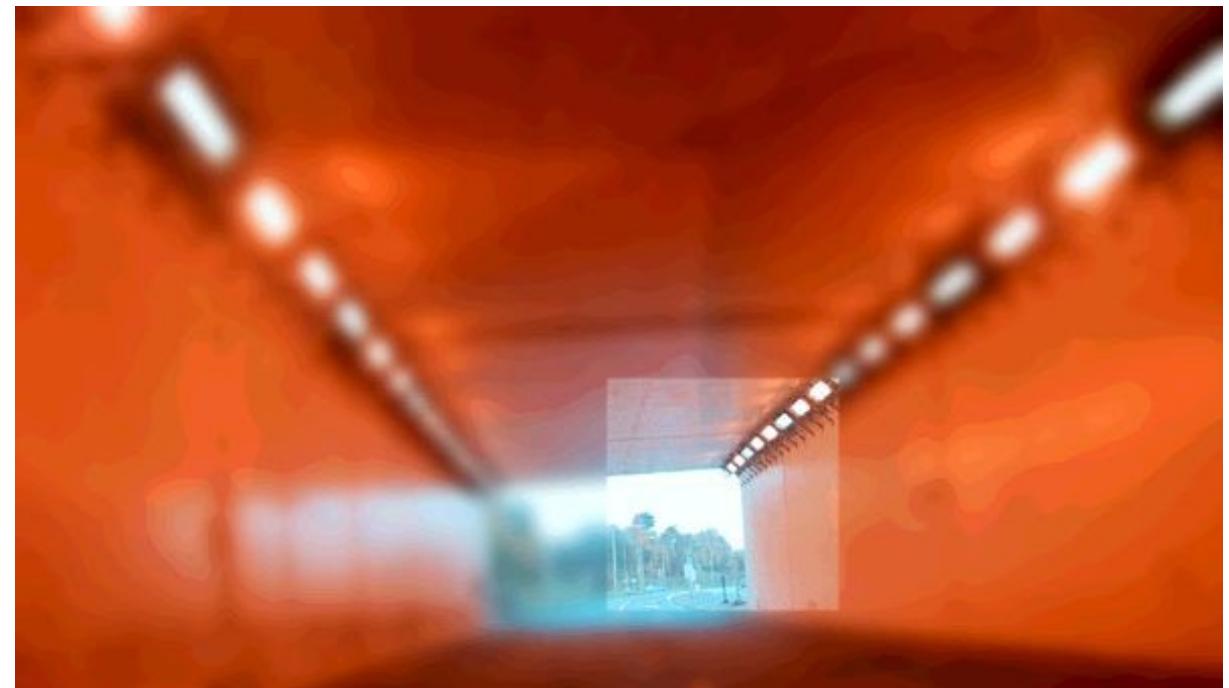

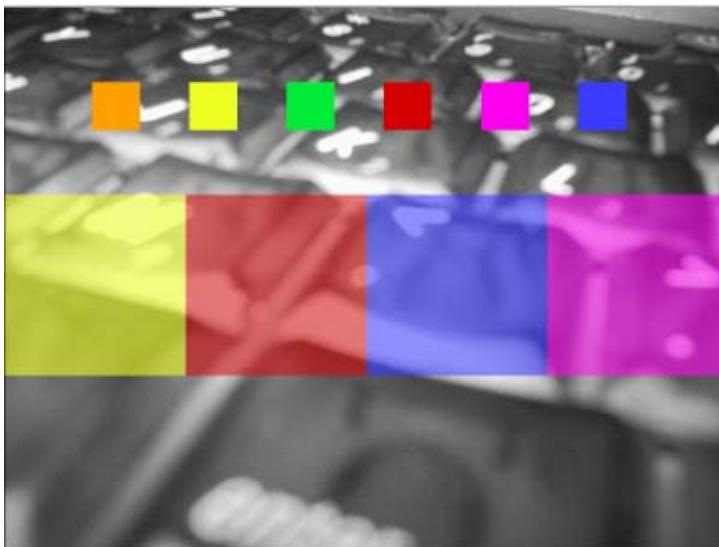

- ***This is from an alternative solution!***
- `saldo_txt` is a `TextField` object generated in the authoring tool
- Text fields cannot be linked to ActionScript classes
- A method can be added as follows (in main timeline):

```
saldo_txt.update = function(){
    var saldo: Number = myAccount.getSaldo();
    saldo_txt.text = saldo;
    if (saldo < 0)
        lowWarning_mc.gotoAndPlay("startAnim");
    else
        lowWarning_mc.gotoAndStop("stopAnim");
}
```

# Further Literature (German)

# Sounds in the Library

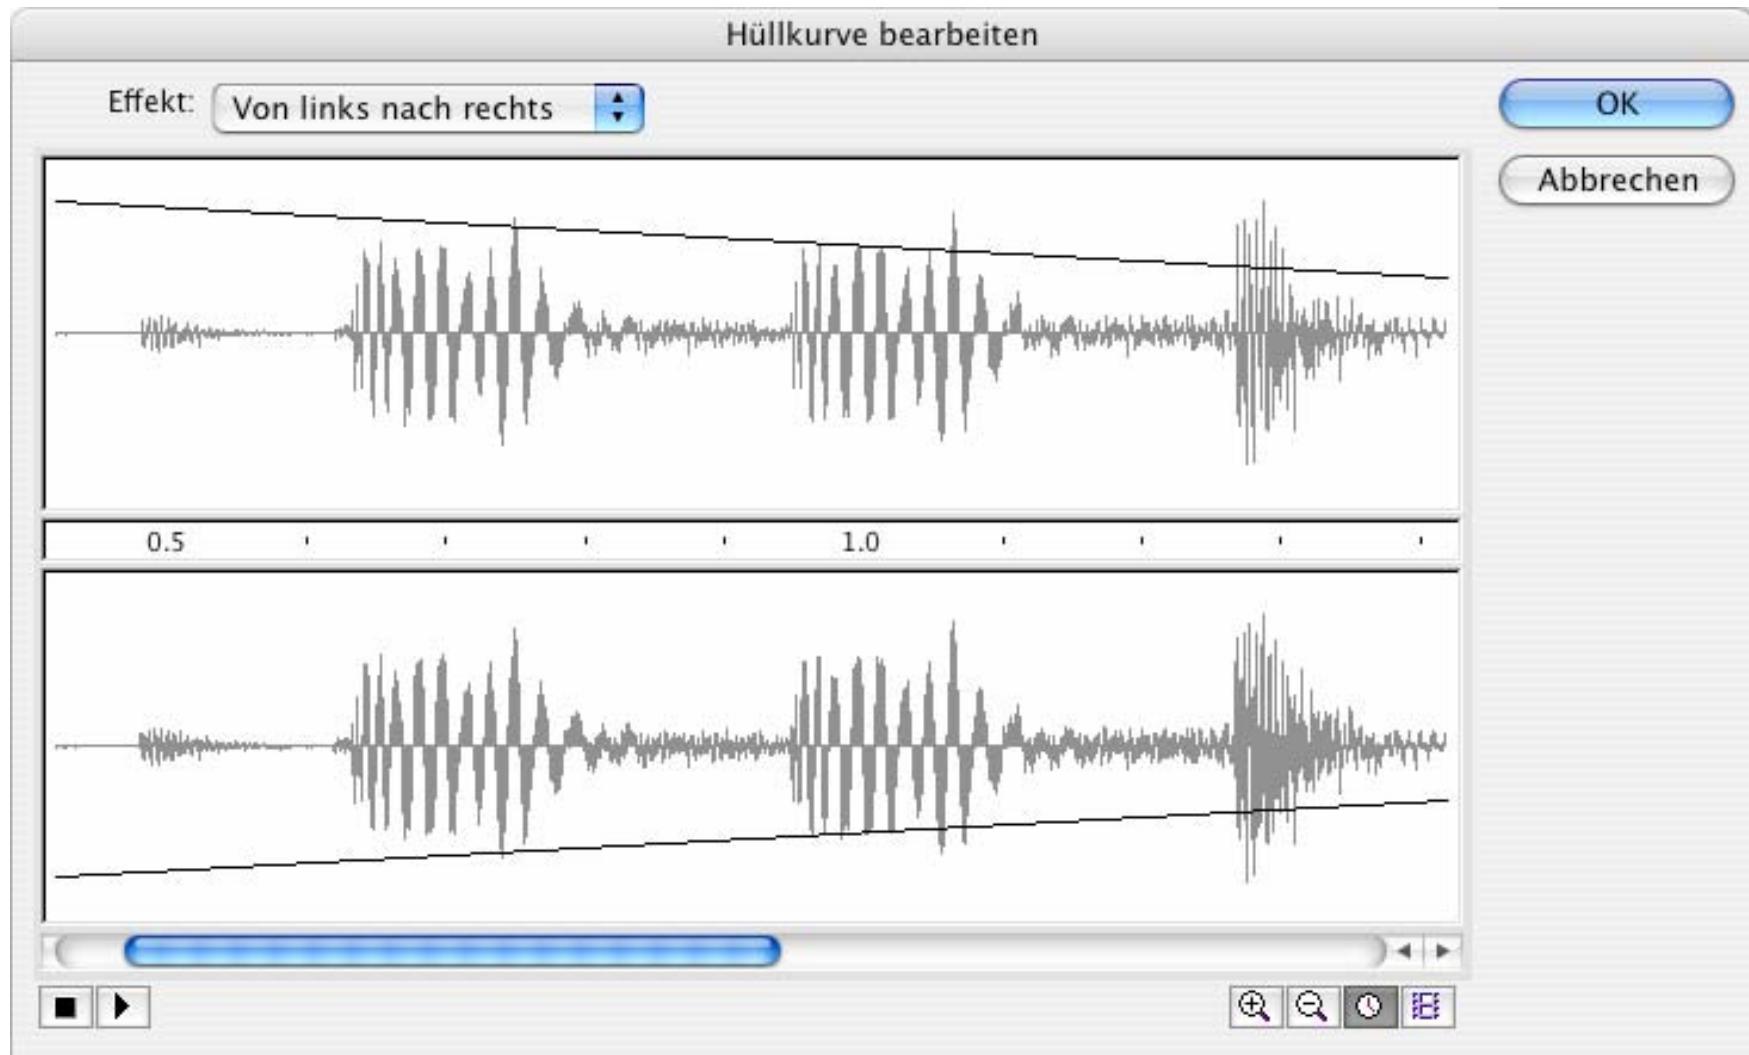

- Sounds are imported from a file (in Flash essentially WAV, MP3, AU)
  - Flash command:  
File -> Import -> Import into Library
- Sounds in the library are the raw material to be used in further design

# Sound Processing in Authoring Tool

- Some simple effects can be created graphically

# Sound Objects in Time-based Animations

- Sound object:
  - Encapsulates a (pre-produced) sound clip
- A sound object is associated with a specific timeline
  - Sound is played as the time in the timeline progresses
  - There may be many sounds in one presentation
    - » Main timeline
    - » Individual movie clip instance timelines
  - Sounds are mixed together
- Association of sound instance (from library) to timeline
  - Either graphically (e.g. dragging sound onto frame)
  - or using ActionScript method `attachSound()`

# ActionScript Syntax for Sound Objects

- Creating a sound object:

```
var soundObjectName:Sound = new Sound(TargetClip);
```

Example:

```
var mySound:Sound = new Sound(myMovieClip_mc);
```

Omitting the *TargetClip*: Definition of global sound

- A Sound object is a *handle* like the Color object
- Controlling the sound's volume:

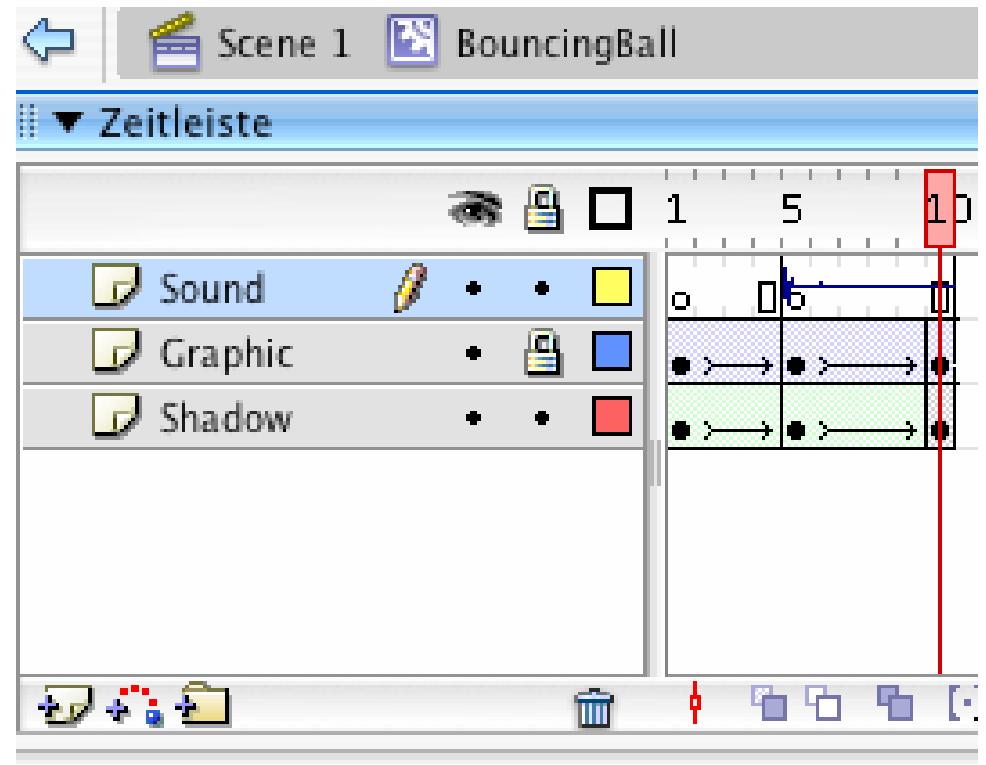

```
mySound.setVolume(50);
```

- Attaching a library sound:

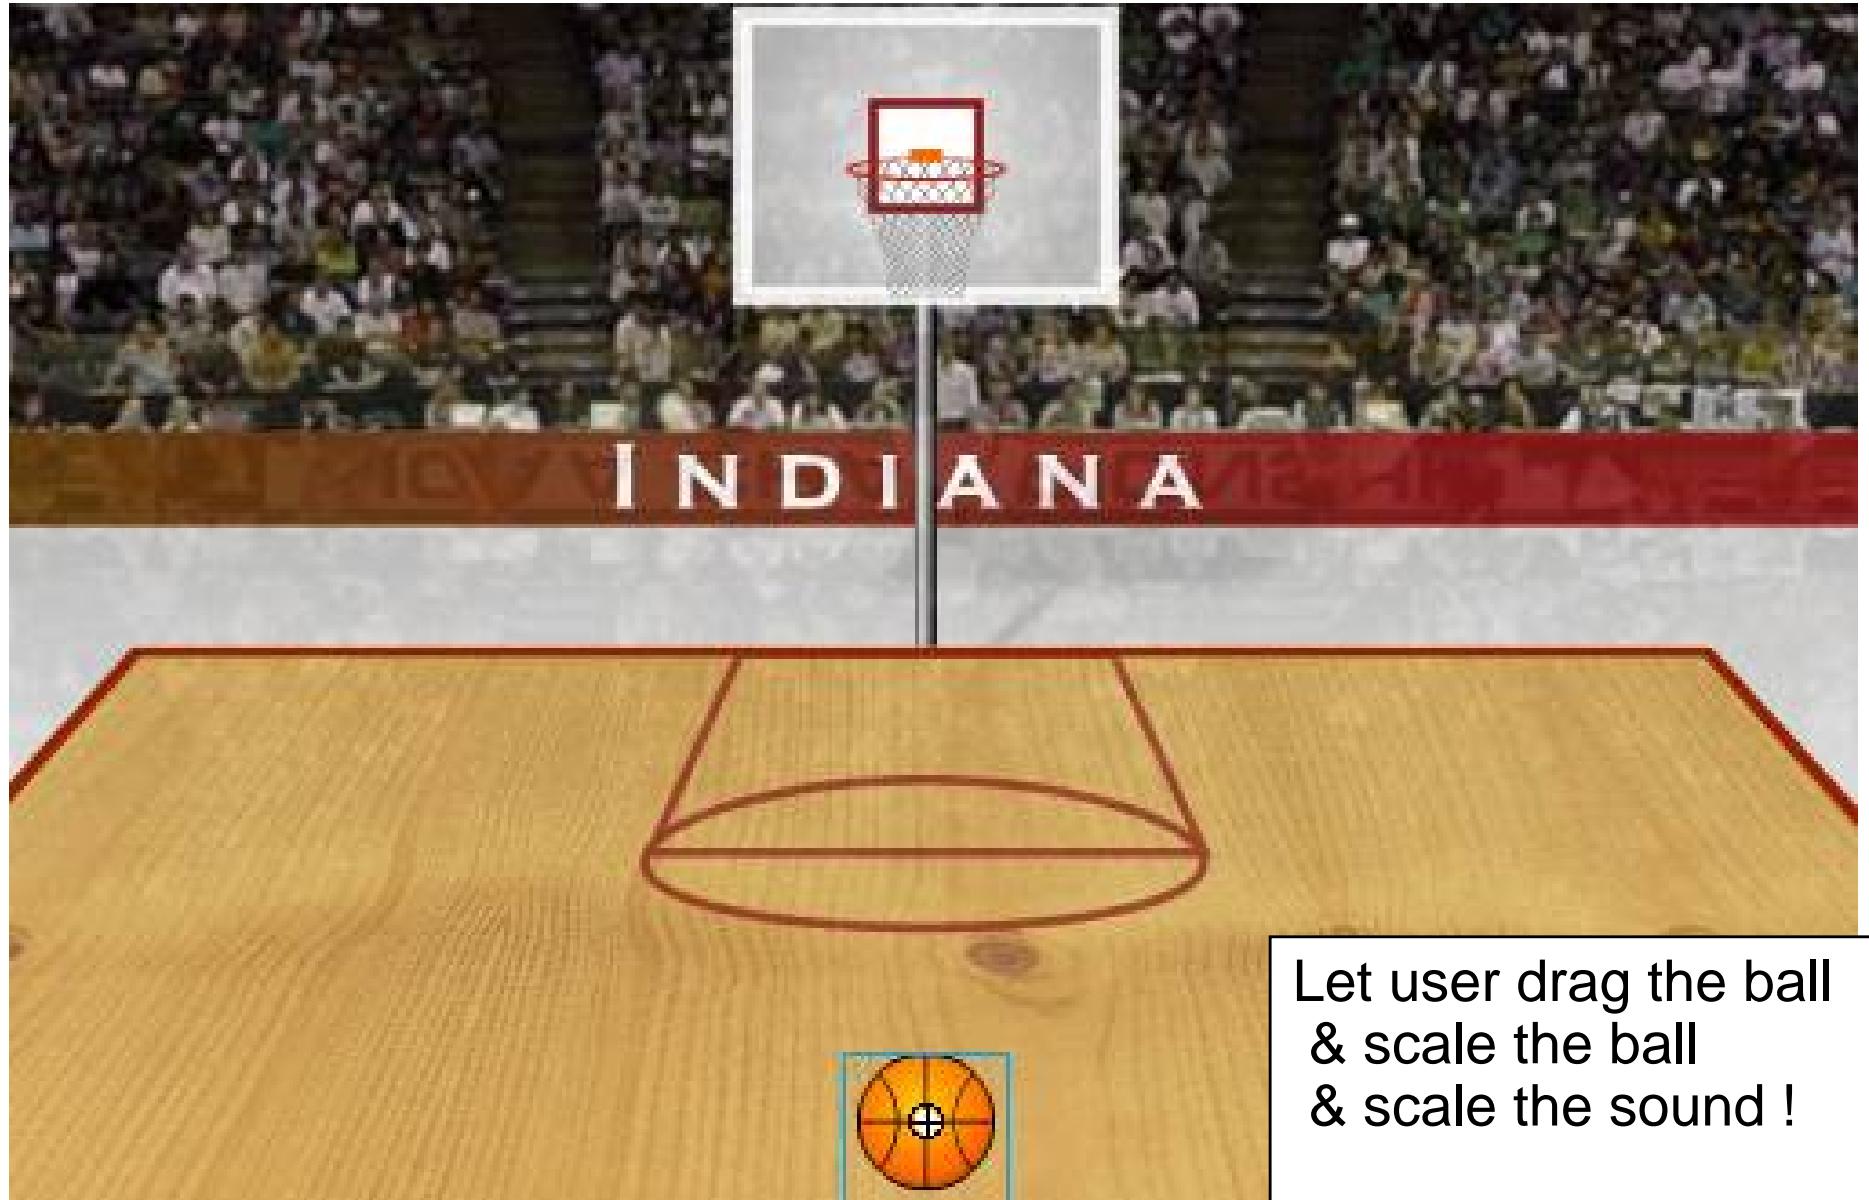

```
mySound.attachSound("rockMusic");
```

# Example: A Bouncing Basketball

- Library contains the sound of the bouncing ball
- Movement of ball and coordinated change of shadow realised by tweening
- At the frame where ball touches ground (frame 5), sound is activated (e.g. through the object inspector)
- Sound is played from frame 5 till end of clip
  - Works only well with short sounds

# Dragging the Ball over the Court

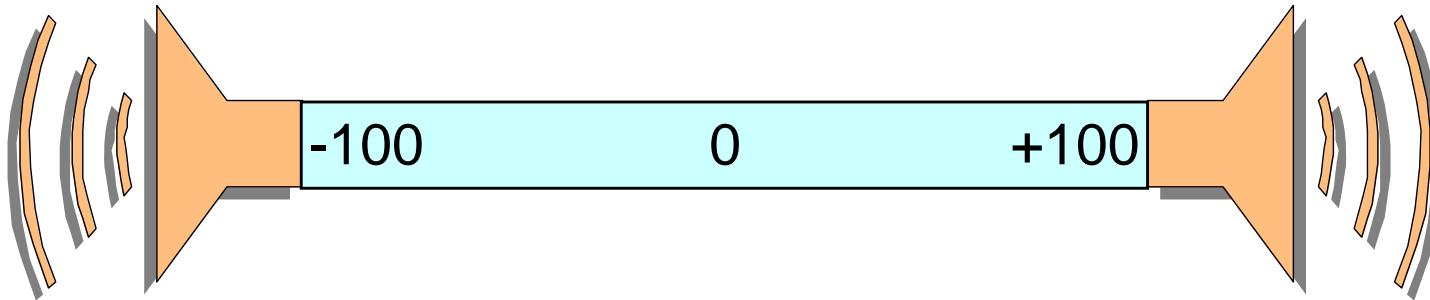

Let user drag the ball  
& scale the ball  
& scale the sound !

# Dynamic Adjustment of Volume (and Scale)

```
var bounce:Sound = new Sound(basketball_mc);
var leftBoundary:Number = 60;
var rightBoundary:Number = 490;
var topBoundary:Number = 220;
var bottomBoundary:Number = 360;
var boundaryHeight:Number = bottomBoundary - topBoundary;

this.onMouseMove = function() {
    if (_xmouse > leftBoundary && _ymouse > topBoundary &&
        _xmouse < rightBoundary && _ymouse < bottomBoundary) {
        basketball_mc.startDrag(true);
        var topToBottomPercent = (((_ymouse - topBoundary) /
            boundaryHeight) * 100) / 2 + 50;
        bounce.setVolume(topToBottomPercent);
        basketball_mc._xscale = topToBottomPercent;
        basketball_mc._yscale = topToBottomPercent;
    } else {
        stopDrag();
    }
}
```

# Stereo Effect: “Panning”

- Panorama position or “balance”:
  - Relative volume of left and right stereo channel
  - Controls the perceived location of a monaural audio signal
- ActionScript (Class **Sound**):
  - Method **setPan(relativeValue)**
  - Only left channel: -100
  - Only right channel: +100
  - Centered: 0

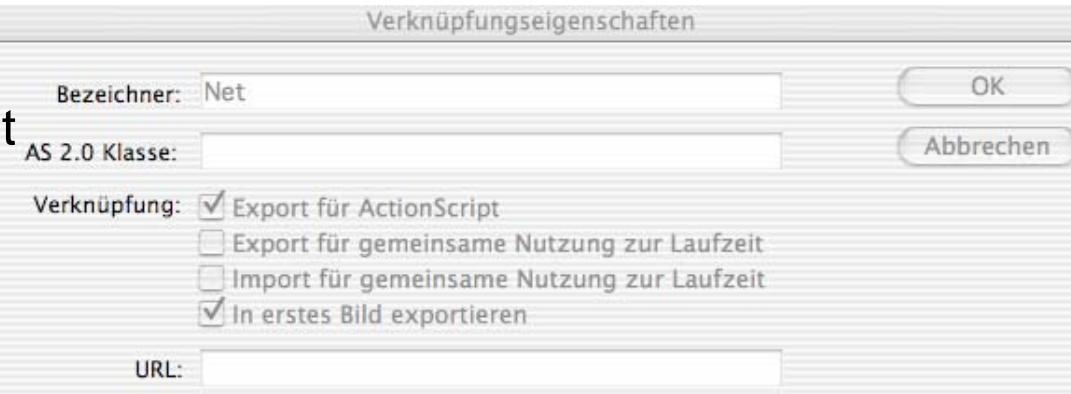

# Example: Stereo Effect for Basketball

- Sound of bouncing ball draggable with mouse to left and right
  - According adjustment of sound balance

```
var leftBoundary, rightBoundary,  
    topBoundary, bottomBoundary...  
  
var boundaryHeight:Number = bottomBoundary - topBoundary;  
var boundaryWidth:Number = rightBoundary - leftBoundary;  
var quadrantSize:Number = boundaryWidth / 2;  
var centerPoint:Number = rightBoundary - quadrantSize;  
  
this.onMouseMove = function() {  
    if (_xmouse > leftBoundary && _ymouse > topBoundary &&  
        _xmouse < rightBoundary && _ymouse < bottomBoundary) {  
        ...;  
        var panAmount =  
            ((_xmouse - centerPoint) / quadrantSize) * 100;  
        bounce.setPan(panAmount);  
    }...  
}
```

# Dynamically Selected Sounds

- Sounds can be attached at runtime dynamically
  - as global sound and to movie clips
- Prerequisite in Flash:
  - Export library sound for ActionScript

- Attaching a sound from library:

```
Class Sound: attachSound("library name");
```

- Playing the sound:

```
Class Sound: start(starttime, repetitions); //time in secs
```

```
Class Sound: stop();
```

# Example: Random Basketball Sounds

- On mouse click: Random number between 0 and 2
  - 0: score for “North Carolina”    --> sound “boo”                                 (Sound0)
  - 1: score for “Indiana”    --> sound “cheer”   (Sound1)
  - 2: no score    --> sound “referee whistle”   (Sound2)
  - Sound names chosen such that names can be computed from number (variable **dynaSounds**)
- In case of score:
  - Play “net sound”
  - Show basketball score animation (**score\_mc**)
  - Update score fields of respective team (**team\_txt**)

# Code for Random Basketball Sounds

```
var dynaSounds:Sound = new Sound();
var netSound:Sound = new Sound ();
...
this.onMouseDown = function() {
    var randomSound = random(3);
    dynaSounds.attachSound("Sound" + randomSound);
    dynaSounds.start(0, 1);
    if(randomSound == 0) {
        northCarolina_txt.text = Number(northCarolina_txt.text)
            + 2;
        netSound.attachSound("Net");
        netSound.start(0, 1);
        score_mc.gotoAndPlay("Score");
    } else if(randomSound == 1) {
        indiana_txt.text = Number(indiana_txt.text) + 2;
        netSound.attachSound("Net");
        netSound.start(0, 1);
        score_mc.gotoAndPlay("Score");
    }
}
```

# Code for Silencing the Dynamic Sounds

- Sound to be switched off when any key is pressed:
  - *Listener* concept used  
(appropriate for events broadcasted to many recipients)

```
this.onKeyDown = function() {  
    dynaSounds.stop();  
}  
Key.addListener(this);
```

# Playing Video from Animations

- Embedding video information into animation
  - Leads to very large files (SWF files in the case of Flash)
- External video clips:
  - Editable separately with specialized software
  - Progressive download: play during loading
  - Video played at its own frame rate, not at the rate of the animation
- Support for external video in Flash (MX 2004):
  - FLV (Flash Video) format
  - Converters from most well-known video formats to FLV exist
  - Special *Media Components* for easy integration of video
    - » MediaDisplay
    - » MediaController
    - » MediaPlayback (= MediaDisplay + MediaController)
  - Media component can also play back MP3 audio

# Flash Components

- *Software component*: „A **software component** is a unit of composition with contractually specified interfaces and explicit context dependencies only. A software component can be deployed independently and is subject to composition by third parties.“  
ECOOP 1996, Workshop on Component-oriented Programming
- *Flash component*: A reusable unit of Flash design and ActionScript programming with clearly specified parameters and methods. A Flash component encapsulates a ready-made solution that can be incorporated into third-party Flash applications.
- Components delivered with Flash (MX 2004, examples):
  - User Interface components:
    - » Button, CheckBox, ComboBox, DataGrid, DateChooser, Label, ProgressBar, ScrollPane, TextArea, TextInput, Window, ...
  - Data components:
    - » DataHolder, DataSet, WebServiceConnector, ...
  - Manager:
    - » PopUpManager, Depth Manager, ...
  - Media Components ...

# Example Flash Component: Date Chooser

- Layout and basic behaviour pre-defined
- Component inspector allows customization, e.g.
  - Definition of string representation for days, months
  - Disabled days (not choosable)
  - Start day of week
- API allows dynamic ActionScript-based adaptation
  - E.g. setting selected date
- Components generate events

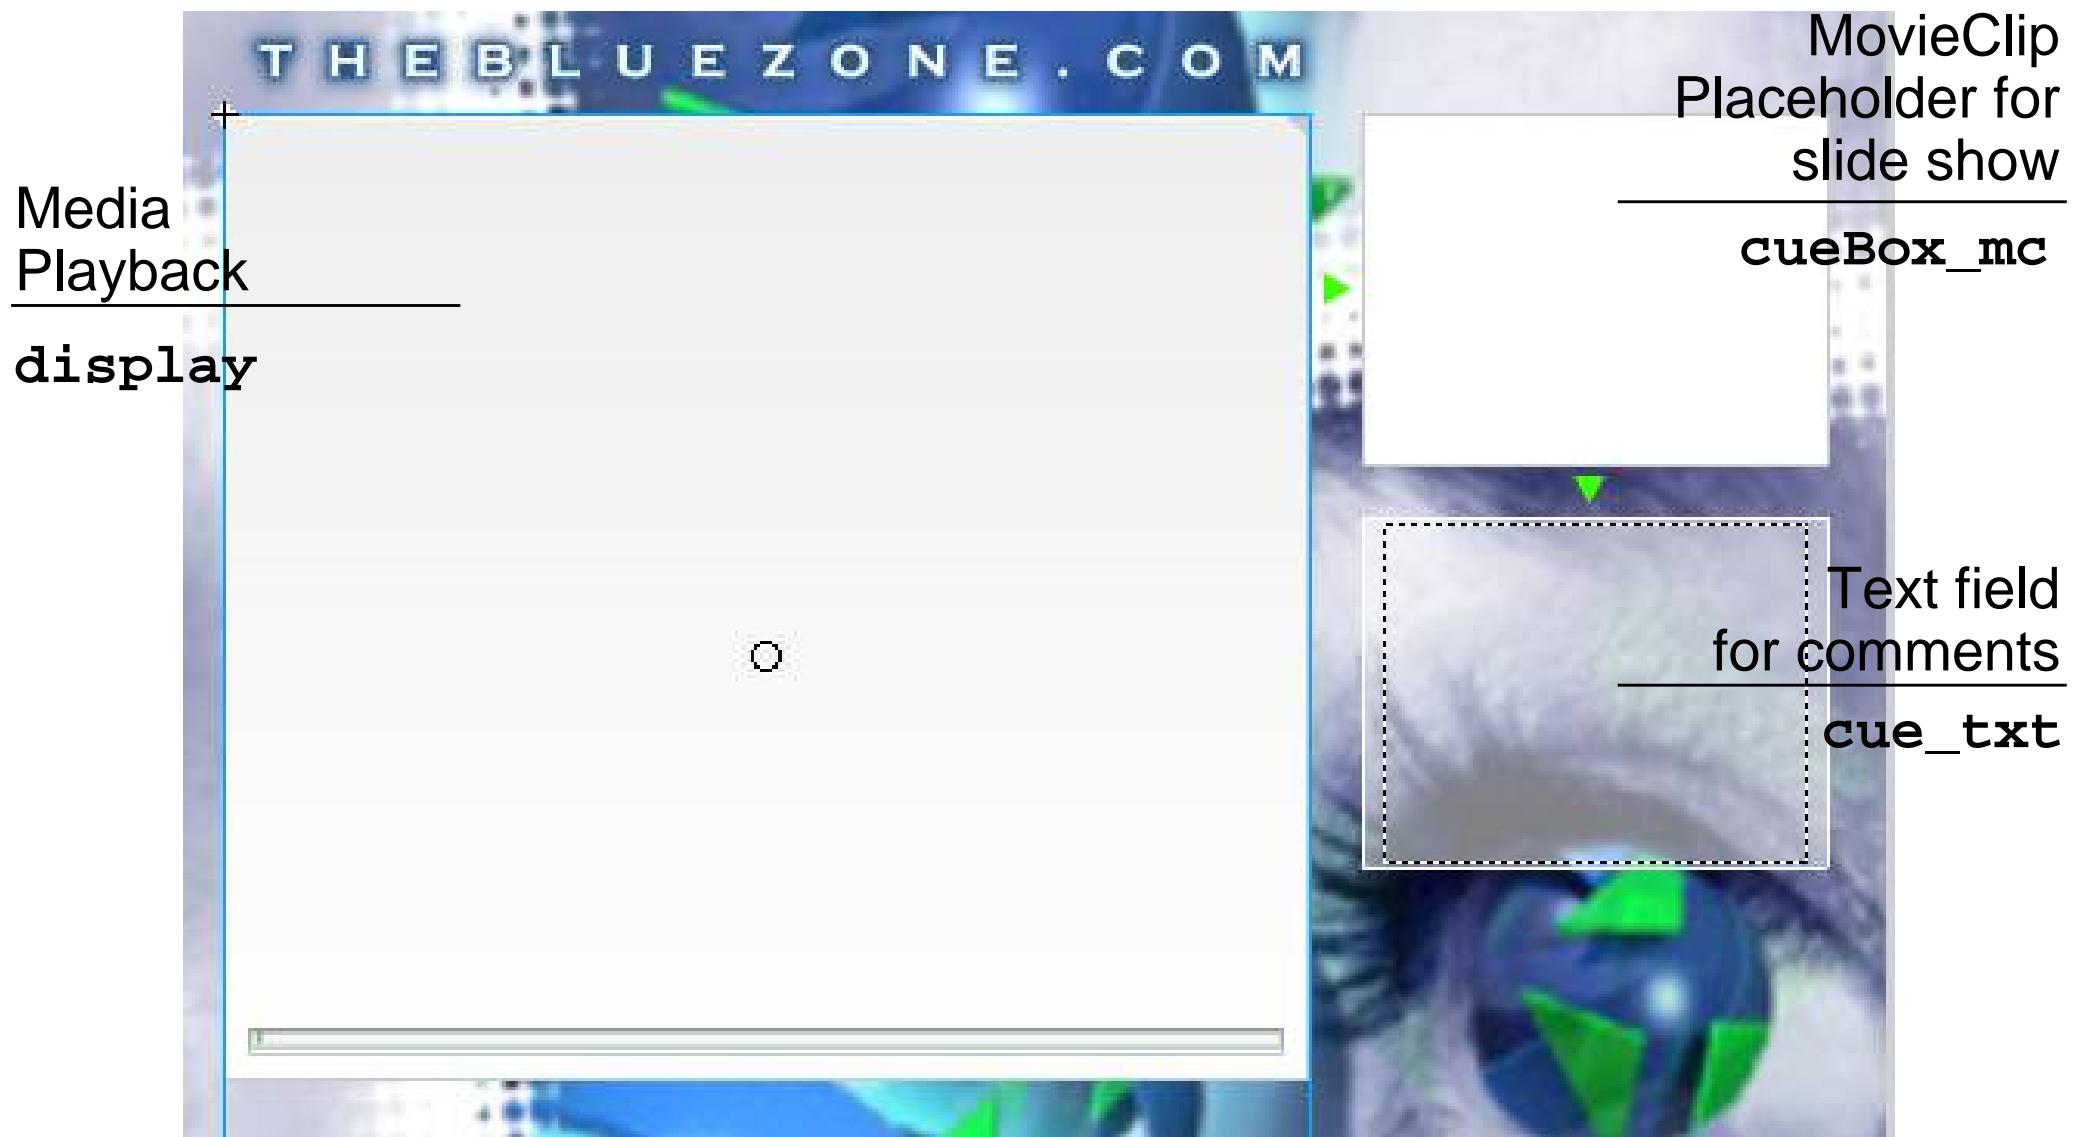

# Events Generated by Media Components

- Various events are reported by Media Components to the surrounding application for flexible reaction:
  - Adjustments like change of volume
  - Media events like reaching end of media
  - User-defined events when reaching specific positions (*cue events*)
- Reaction to media events requires *Listener* objects, e.g.

```
var myListener:Object = new Object();
myListener.volume = function() {
    // actions to react on volume change
}
myMediaComponent.addEventListener("volume", myListener);
```

# Example: Video with Event-Triggered Animation

# Cue Points

- A *cue point* marks a specific point in time during media playback.
  - Cue points can be defined independently of the movie (in ActionScript)
  - When reaching a cue point, an event is fired which can be handled by ActionScript.

```
display.addCuePoint("0", 1);
display.addCuePoint("1", 8);
display.addCuePoint("2", 14);
display.addCuePoint("3", 31);
display.addCuePoint("4", 35);
display.addCuePoint("5", 53);
display.addCuePoint("6", 56);
display.addEventListener("cuePoint", displayListener);
displayListener.cuePoint = function(eventObj:Object){
    var index = Number(eventObj.target.name);
    loadMovie("cue" + index + ".jpg", "cueBox_mc");
    cue_txt.text = cueTextArea[index];
}
```

# Example for Cue Points

- Names of cue points chosen in a way such that conversion to number gives an index
- Two arrays of information to be displayed in the two extra windows
  - Still pictures
  - Text information

cue2.jpg

“Fluffy is crammed  
into dial-up pipe”

cueTextArea[2]

# Flash Pattern: Names and Numbers

- **Problem:** Indexing and computing an index requires numbers to identify information instances. Storage in files and symbol identifiers require strings to identify information instances.
- **Solution:**
  - When a string is required to be used as an index: Choose a string representing a number and convert to number when required with function `Number()`
  - When a number is required to be used as a string: Compute an appropriate String by concatenating a base string with the number. Choose file names and identifiers appropriately.
- **Known Uses:**
  - String-to-Number: Cue point names in above example
  - Number-to-String: File names for CueX pictures in above example; Sound names in Basketball example
